INTERLEUKIN mRNA CHANGES IN MAST CELLS STIMULATED BY TSL-1 ANTIGENS

Summary:
In this work we analyzed by RT-PCR, the mRNA changes for IL-4, IL-10, TNF and IFNγ induced by TSL-1 antigens in a rat mast cell line (HRMC) with mucosal characteristics. The data obtained showed an increase of 65% and 52% in mRNA expression for IL-4 and TNF respectively and a decrease of 59% and 55% in mRNAs for IFNγ and IL-10. Our results suggest that TSL-1 antigens induce the release from MC of regulatory molecules, such as IL-4 by an IgE independent mechanism. Our data also provides important information related to the ability of MC to participate not only in the effector phase against the infectious agents, but also in the orchestration of the immune response by the host against parasites.

KEYWORDS: mast cell, activation, TSL-1 antigens, RT-PCR, Trichinella spiralis

Mast cell (MC) degranulation at sites of invasion by pathogens has a protective role for the host. In this regard, MC are phagocytic towards bacteria and the release of TNF by MC induces the recruitment of neutrophils to the site of Klebsiella pneumoniae infection. It has been well documented that MC can be activated by direct contact with other bacteria such as E. coli and also by protozoa parasites such as Leishmania major and L. infantum, making them important elements in innate immunity (Bidri et al., 1997; Malaviya et al., 1999). Recently, we have demonstrated IgE independent activation of MC by Trichinella spiralis antigens (TSL-1 antigens) evaluating as activation markers the release of histamine, protease 5 (P5) and TNFα (Arizmendi et al., 1997). Particularly, peritoneal MC (PMC) obtained from non-sensitized rats, showed the maximum release of P5 and histamine when 30 ng/ml of TSL-1 antigens were used. On the other hand, it has been suggested that interleukins (mainly IL-4) produced by MC in response to helminthic antigens can actively participate in the early induction of Th2 type response in intestinal helminthic infections (Romagnani, 1992). Therefore, we determined if the direct activation of MC by TSL-1 antigens, induce changes in mRNA expression of specific MC interleukin mRNAs, mainly IL-4, IL-10, TNF and IFNγ.

MATERIAL AND METHODS

PARASITES AND ANTIGENS

T. spiralis (MSUS/MEX/91 CM-91) was maintained in Sprague Dawley rats and muscle larvae (ML) were recovered by acid-pepsin digestion (Dennis et al.,1970). Purification of TSL-1 antigens was carried out as recommended by Ortega-Pierres et al. (1989).

HRMC CULTURES AND STIMULATION WITH TSL-1 ANTIGENS

HRMC, a rat mast cell line, with characteristics of mucosal mast cell, was kindly provided by Dr. A. Froese, University of Manitoba, Canada. One $10^6$ HRMC cells were incubated at 37°C in a humidified atmosphere containing 5% CO2 in RPMI-1640 medium supplemented with 10% fetal bovine serum (FBS) for eight hours in the presence of 30 ng/ml of TSL-1 antigens (surface antigens purified from T. spiralis ML). HRMC without treatment was included as negative control.

RT-PCR ASSAYS

Total RNA from HRMC cells stimulated with TSL-1 antigens was prepared following the procedure described by Chomcynski and Sacchi (1987). Two μg of total RNA were then converted to single stranded cDNA by using Expand RT enzyme, according to the provider’s instructions (Boehringer Mannheim, Germany). PCR amplification was carried out using specific primers for rat IL-4, IL-10, TNF, IFNγ and β actin (Table I). The amplified products were separated by agarose gel electrophoresis and visualized under UV transilluminator by staining with ethidium bromide. The amplification products were quantified by densitometry (Genetools Program, Synoptics, Cambridge, Germany).

Table I. – PCR primers specific for rat IL-4, IL-10, TNF, IFNy and β actin.

Table II. – Densitometric analysis of interleukin mRNA changes in MC induced by TSL-1 antigens.

RESULTS

The PCR amplification products from each interleukin (Fig. 1) were analyzed by densitometry, and values were normalized to β actin amplification product (these data are representative of three experiments). These values were compared to the negative control as a percentage of increase or decrease (Table II). From this analysis, we observed an increase of 65 and 52 % in mRNA expression for IL-4 and TNF respectively and a decrease of 59 and 55 % in mRNAs for IFNy and IL-10 respectively.

DISCUSSION

Mast cell populations from different species and sites can be activated by secretagogues arising from a variety of sources. It has been suggested that MC play an important role in both acquired and innate immune responses in the host. Recently it has been demonstrated that MC can release TNF as a result of direct activation by bacterial and parasite antigens (Bidri et al., 1997; Malaviya et al., 1999). In this regard, we have previously demonstrated that PMC are activated by TSL-1 antigens by an IgE independent mechanism and that as a result of this
activation MC release histamine, P5 and TNF (Arizmendi et al., 1997). On the other hand, given the type of ILs produced by MC and their possible release after direct contact with parasite antigens, these cells can also participate not only in the effector phase against the infectious agents, but they can regulate the immune response that is induced in the host against them. Thus, we demonstrated that MC can increase their mRNA levels for IL-4 and TNF, whereas they decrease mRNA levels for IFNγ and IL-10 by direct contact with TSL-1 antigens. The results obtained in this study provide important evidence related to the ability of MC to produce mRNA for regulatory molecules, such as IL-4, suggesting that MC could participate in the induction of a preferential TH2 type immune response during intestinal infections by helminths. Together these results place the MC as an important factor in innate immunity.
