Abstract – *Pterygodermatites (Paucipectines) baiomydis* n. sp., an intestinal parasite of the northern pygmy mouse, *Baiomys taylori* (Cricetidae), collected in La Yerbabuena, Colima, Mexico, is described herein. Specimens were studied using light and scanning electronic microscopy. This is the 19th species of the subgenus *Paucipectines* described worldwide and the fourth collected in Mexico. It is differentiated from the remaining species in the subgenus by having 25 perioral denticles, arranged in a triangle (seven on each lateroventral margin, and eleven on the dorsal margin), and 10 pairs of caudal papillae.

Key words: Nematoda, *Pterygodermatites*, *Baiomys taylori*, Rodentia, Cricetidae, Mexico.

Résumé – *Pterygodermatites (Paucipectines) baiomydis* n. sp. (Nematoda: Rictulariidae), parasite de *Baiomys taylori* (Cricetidae). *Pterygodermatites (Paucipectines) baiomydis* n. sp., parasite intestinal du rongeur *Baiomys taylori* (Cricetidae), collecté dans La Yerbabuena, Colima, Mexique, est décrit. Les échantillons ont été étudiés en utilisant microscopie photonique et microscopie électronique à balayage. Ceci est la dix-neuvième espèce du sous-genre *Paucipectines* décrite dans le monde et la quatrième au Mexique. Elle se distingue des autres espèces dans le sous-genre par la possession de 25 denticules périoraux disposés en triangle (sept sur chaque marge latéroventrale et onze sur la marge dorsale) et dix paires de papilles caudales.

Introduction

Cricetid rodents are one of the most speciose groups of mammals of the New World with approximately 600 species [25]. From the 141 species known to occur in Mexico [25], only 25 had been examined for helminths prior to this study. These surveys resulted in the inventory of 45 species of helminths [5].

As part of an ongoing project to describe the metazoan fauna associated with rodents from Mexico, we analyzed 27 cricetid taxa in seven localities from the Mexican states of Colima, Guerrero, Jalisco, Michoacán, and Oaxaca. The main goal of this paper is to describe a new species of the nematode subgenus *Pterygodermatites (Paucipectines)* Quentin, 1969, as

a parasite of the northern pygmy mouse *Baiomys taylori* (Thomas, 1887) in Colima, Mexico.

Materials and methods

In December, 2011, two specimens of *B. taylori* were collected in La Yerbabuena (19°28'39" N, 103°40'46" W) in Comala, Colima, Mexico. Hosts were collected with permission (FAUT-0170), issued by Secretaría del Medio Ambiente y Recursos Naturales, Mexico. Rodents were anesthetized by isoflurane inhalation, euthanized by cervical dislocation, and examined for helminth parasites. Helminths were removed from the intestine and placed in 0.85% saline solution, fixed

(Figs. 1A–1K)

Type host: *Baiomys taylori* (Thomas, 1887) (Rodentia: Cricetidae). Symbiotype deposited at Museo de Zoología Alfonso L. Herrera, Facultad de Ciencias (MZFC-M) de la Universidad Nacional Autónoma de México, Mexico City, Mexico (MZFC-M 11988, 12294). Date of collection: December, 2011.

Type locality: La Yerbabuena (19°37'26.36" N, 103°32'41.20" W), Colima, Mexico.

Site of infection: Intestine.

Prevalence and intensity of infection: two of two hosts examined were infected; mean intensity 3.5, range 1–7.

Figure 3. (K) *Pterygodermatites (Paucipectines) baiomydis* n. sp., a parasite of *Baiomys taylori* from Colima, Mexico. **K.** Left spicule surrounded by folded spicular sheath.

Etymology: The species is named after the host's generic name.

Specimens deposited: Holotype: CNHE 8662 (female); paratypes CNHE 8663 (1 male) and CNHE 8664 (5 females).

Description

General

Medium-sized nematodes, body slightly widened at posterior end, with thick cuticle. Oral opening apical, surrounded by 5 pairs of papillae, 2 cephalic pairs, and 3 internal labial pairs (1 dorsal, 1 ventral and 1 lateroventral pair). Amphids lateral. Oral opening asymmetric, somewhat hexagonal, with thick margins. Seven denticles on lateroventral margins, and 11 denticles on dorsal margin; 3 internal pharyngeal teeth at bottom of buccal capsule, 1 dorsal and 2 lateroventral. Two subventral rows of cuticular projections along body, starting at end of buccal capsule and ending at anus in females and at level of ventral fans in males. A single type of cuticular projection present in males (combs), and 2 different types in females: simple spines and combs.

Esophagus divided into short muscular and long glandular portions.

Male (based on the paratype)

Total length 2.93 mm, width at base of buccal capsule 0.1. Buccal cavity 27 deep by 45 wide in lateral view. Number of perioral denticles undetermined. Three esophageal teeth, 10 long. Esophagus not measured. Nerve ring located 210 from anterior end. Deirids and excretory pore not observed. Forty-two pairs of subventral combs, 32–89 (69 ± 18 , $n = 10$) long, and three ventral cuticular fans anterior to cloaca (*sensu* Lichtenfels [8]). Anterior fan 47 long, second and third fan, 30 long. Tail length 110. Spicules markedly unequal, curved ventrally, with blunt tips; left 110 long (Fig. 3K); right spicule

simple, 47 long. Gubernaculum 10 long. Ten pairs of caudal papillae: 2 precloacal pairs, 1 at distal base of third fan and 1 between third fan and cloaca; 8 postcloacal pairs: 1 sublateral pair near cloaca, followed by 4 subventral pairs and 1 sublateral pair, the latter at same distance from cloaca as the last subventral pair; the last 2 pairs subventral and subterminal (Fig. 1D). Phasmids posterior to caudal papillae.

Female (based on the holotype and five paratypes)

Total length 18.35–21.41 (20.06 ± 1.4 , $n = 5$) mm, prevulvar width 210–310 (280 ± 40 , $n = 5$), postvulvar width 300–450 (340 ± 60 , $n = 5$). Buccal cavity 90–120 (100 ± 23 , $n = 5$) deep by 70–110 (100 ± 14 , $n = 5$) wide in lateral view (Fig. 1C). Twenty-five perioral denticles 6.51–9.76 (7.80 ± 1 , $n = 25$) long, arranged in triangle (7 on each lateroventral margin, and 11 on dorsal margin; Fig. 2H). Three esophageal teeth 20–40 (30 ± 5 , $n = 15$) long (Fig. 1B). Total length of esophagus 2260–2650 (2470 ± 140 , $n = 5$) (13.6% of body length), muscular portion 310–440 (380 ± 70 , $n = 3$) long, 50–70 (60 ± 8 , $n = 3$) wide at level of nerve ring; glandular portion 1630–1860 (1710 ± 130 , $n = 3$) long, 80–110 (94 ± 10 , $n = 3$) wide. Nerve ring and deirids located 210–350 (280 ± 70 , $n = 5$) and 460–660 (560 ± 100 , $n = 4$) from anterior end, respectively (Fig. 1A). Excretory pore not observed. Vulva 2220–3950 (3420 ± 780 , $n = 5$) from anterior end and 770–1830 (1190 ± 410 , $n = 5$) from esophago-intestinal junction, at level of the 42nd cuticular projection. Two subventral rows with 64–75 (71 ± 3.54 , $n = 5$) cuticular projections (Figs. 2G and 2H); 38–44 (42 ± 2.53 , $n = 5$) prevulvar combs (Fig. 1F) and 25–31 (29 ± 2.22 , $n = 5$) postvulvar spines (Fig. 1E); –16 (12 ± 2.13 , $n = 5$) combs between posterior end of esophagus and vulva. Maximum length of combs and spines 100–220 (160 ± 50 , $n = 5$) and 130–240 (170 ± 40 , $n = 5$), respectively. Last spine located 1020–2108 (1632 ± 420 , $n = 5$) from posterior end. Tail 160–250 (210 ± 20 , $n = 5$) long (Fig. 2J). Larvated eggs 30–40 (31 ± 4 , $n = 10$) by 15–34 (25 ± 4 , $n = 10$).

Remarks

The morphology of the buccal capsule of the specimens described in this study, particularly the apical position of the oral opening, enables us to include them in the subgenus *Pterygodermatites (Paucipectines)* [3]. However, the number of prevulvar cuticular processes in *P. (Paucipectines) baiomydis* n. sp. (38–44) differs from the range described for the subgenus (29–39) by Quentin [19]. Because variations of this trait have been reported for other species included in the subgenus, for example *P. (P.) kozeki* (Chabaud and Bain, 1981), *P. (P.) jagerskioldi* (Lent and Freitas, 1935), and *P. (P.) dipodomis* (Tiner, 1948), all possessing more than 39 prevulvar cuticular processes, the diagnosis of this subgenus should be amended (Table 1).

To date, 18 species of this subgenus have been described as parasites of rodents (12 species), armadillos (1 species), bats (1 species), and marsupials (4 species) (Table 1). *Pterygodermatites (P.) baiomydis* most closely resembles

Table 1. Selected features of the species included in the subgenus *Pterygodermatites* (*Paucipectines*) worldwide.

* DN = Number of denticles.

† CP: p/u = Caudal papillae: paired/unpaired.

P. (P.) dipodomis and *P. (P.) zygodontomys* (Quentin, 1967). All three species share traits such as the number of prevulvar combs and fans, unequal spicules, and all three parasitize rodents (Table 1). However, the number of denticles is greater in *P. (P.) baiomydis* (25 vs. 18 and 17–21, respectively); the distance from the last spine to the tip of the tail in females of *P. (P.) zygodontomys* is smaller (770), and the distance from the vulva to the esophago-intestinal junction in *P. (P.) baiomydis* is greater (1190) than in the other two species (730 and 580, respectively). *Pterygodermatites (P.) zygodontomys* features an unpaired papilla, which makes it different from *P. (P.) baiomydis*. The new species differs from *P. (P.) dipodomis* by the rounded oral opening, and the smaller number of caudal papillae (9 vs. 10).

In addition, *P. (P.) baiomydis* can be differentiated from *P. (P.) elegans* (Travassos, 1928), *P. (P.) coloradensis* (Hall, 1916) [6], and *P. (P.) parkeri* Lichtenfels, 1970, because these three species lack fans and have unpaired caudal papillae, whereas the new species has three fans and all papillae are paired. From *P. (P.) hymanae* Jiménez and Patterson, 2012, *P. (P.) jägerskioldi*, and *P. (P.) spinicaudatis* Navone and Suriano, 1992, the new species is distinguished based on the number of perioral denticles (14, 16, and 11–12, respectively vs. 25 in *P. (P.) baiomydis*), as well as the host group (marsupials vs. rodents) and distribution (South America vs. North America). The number of fans and spicule size allow us to differentiate *P. (P.) kozeki*, *P. (P.) ondatrae* (Chandler, 1941) and *P. (P.) microti* (McPherson and Tiner, 1952) from the new species, since these three species have only one fan (instead of three fans as in the new species) and their spicules are almost equal in size, whereas in *P. (P.) baiomydis* spicules are unequal. Two other species, *P. (P.) peromysci* Lichtenfels, 1970 and *P. (P.) onychomis* (Cuckler, 1939), differ from the new species by the position of the vulva, which in those species is anterior to the esophago-intestinal junction, whereas in *P. (P.) baiomydis* it is situated 1190 posterior to the esophago-intestinal junction. Moreover, the oral opening in *P. (P.) peromysci* and *P. (P.) onychomis* is a rounded oval, but hexagonal in the new species. In having fewer denticles, arranged in a trapezoid, *P. (P.) chaetophracti* (Navone and Lombardero, 1980) and *P. (P.) azarai* (Sutton, 1984) can be distinguished from the Mexican species (16–18 and 17–19, respectively vs. 25 disposed in a hexagon).

For most of the species of the subgenus, males are unknown or insufficiently described; for that reason, female morphological traits are commonly used in species differentiation, partially solving this problem. However, in species such as *P. (P.) massoi* (Sutton, 1979), females are poorly described and the morphology of males is still unknown. Because of this, we only compared a few characters of this species with our material; nonetheless, the following traits are sufficient to distinguish them: body size 8.44–9.1 mm in Sutton's species vs. 18.35–21.41 mm in *P. (P.) baiomydis*; distance from the last spine to the tip of the tail (108 vs. 1660), and distribution (South America vs. North America).

Besides their distribution (Russia), *P. (P.) baicalensis* (Spassky, Ryzhikov and Sudarikov, 1952) and *P. (P.) sibiricensis* (Morozov, 1959) differ from the new species in having

fewer prevulvar combs (31, 33–34, and 38–44, respectively). In addition, *P. (P.) baicalensis* has 18 bicuspid perioral denticles (instead of 25 unicuspid ones), and the shape of the oral opening of *P. (P.) sibiricensis* is rectangular, not hexagonal.

Pterygodermatites (Paucepectines) baiomydis is the 19th species of the subgenus described worldwide and the fourth collected in Mexico. Since cricetid rodents are one of the most speciose groups of mammals of the New World with approximately 600 species [25], its helminth fauna is incompletely documented. From the 141 cricetid species known to occur in Mexico [25], only 26 have been examined for helminths. The surveys of more species of this host group could result in the description of numerous new species of helminths, including representatives of *Pterygodermatites*.

PARASITE

An international open-access, peer-reviewed, online journal publishing high quality papers on all aspects of human and animal parasitology

Reviews, articles and short notes may be submitted. Fields include, but are not limited to: general, medical and veterinary parasitology; morphology, including ultrastructure; parasite systematics, including entomology, acarology, helminthology and protistology, and molecular analyses; molecular biology and biochemistry; immunology of parasitic diseases; host-parasite relationships; ecology and life history of parasites; epidemiology; therapeutics; new diagnostic tools.

All papers in Parasite are published in English. Manuscripts should have a broad interest and must not have been published or submitted elsewhere. No limit is imposed on the length of manuscripts.

Parasite (open-access) continues **Parasite** (print and online editions, 1994-2012) and **Annales de Parasitologie Humaine et Comparée** (1923-1993) and is the official journal of the Société Française de Parasitologie.

Editor-in-Chief:
Jean-Lou Justine, Paris
